Upper Bounds for the Number of Solutions to Quartic Thue Equations
Oberwolfach Preprints (OWP)

Starting in 2007, the MFO publishes a preprint series which mainly contains research results related to a longer stay in Oberwolfach. In particular, this concerns the Research in Pairs-Programme (RiP) and the Oberwolfach-Leibniz-Fellows (OWLF), but this can also include an Oberwolfach Lecture, for example.

A preprint can have a size from 1 - 200 pages, and the MFO will publish it on its website as well as by hard copy. Every RiP group or Oberwolfach-Leibniz-Fellow may receive on request 30 free hard copies (DIN A4, black and white copy) by surface mail.

Of course, the full copy right is left to the authors. The MFO only needs the right to publish it on its website www.mfo.de as a documentation of the research work done at the MFO, which you are accepting by sending us your file.

In case of interest, please send a pdf file of your preprint by email to rip@mfo.de or owlf@mfo.de, respectively. The file should be sent to the MFO within 12 months after your stay as RiP or OWLF at the MFO.

There are no requirements for the format of the preprint, except that the introduction should contain a short appreciation and that the paper size (respectively format) should be DIN A4, "letter" or "article".

On the front page of the hard copies, which contains the logo of the MFO, title and authors, we shall add a running number (20XX - XX).

We cordially invite the researchers within the RiP or OWLF programme to make use of this offer and would like to thank you in advance for your cooperation.

UPPER BOUNDS FOR THE NUMBER OF SOLUTIONS TO QUARTIC THUE EQUATIONS

SHABNAM AKHTARI

Abstract. We will give upper bounds for the number of integral solutions to quartic Thue equations. Our main tool here is a logarithmic curve \( \phi(x, y) \) that allows us to use the theory of linear forms in logarithms. This manuscript improves the results of author’s earlier work with Okazaki [2] by giving special treatments to forms with respect to their signature.

1. Introduction

In this paper, we will study binary quartic forms with integer coefficients; i.e. polynomials of the shape

\[ F(x, y) = a_0 x^4 + a_1 x^3 y + a_2 x^2 y^2 + a_3 x y^3 + a_4 y^4, \]

with \( a_i \in \mathbb{Z}, \ i \in \{0, 1, 2, 3, 4\} \). We aim to give upper bounds for the number of solutions to the equation

\[ |F(x, y)| = 1. \]

Here we will count \((x, y)\) and \((-x, -y)\) as one solution. Let \( M(F) \) be the Mahler measure of \( F(x, y) \). In [2] we used some ideas of Stewart [16] to bound the number of solutions with \(|y| < M(F)^6\). We will slightly modify those ideas and use them to give an upper bound for the solutions of (1) with \(|y| < M(F)^{3.5}\). Then we will improve the main result in [2] by giving better upper bounds for the number of solutions \((x, y)\) with large \(|y| \geq M(F)^{3.5}\) to equation (1). The following is the main result of this manuscript.

**Theorem 1.1.** Let \( F(x, y) \) be an irreducible quartic binary form with integer coefficients. The Diophantine equation (1) has at most \( U_F \) (see the table below) solutions in integers \( x \) and \( y \), provided that the discriminant of \( F \) is greater than \( D_0 \), where \( D_0 \) is an explicitly computable constant.

Key words and phrases. Thue Equations, Linear Forms in Logarithms.
The reason for having different upper bounds for forms with different signature in Theorem 1.1, relies upon the fact that the number fields generated over \( \mathbb{Q} \) by a root of the equation \( F(x, 1) = 0 \) have a rings integers with different numbers of fundamental units.

One can use the method of this manuscript to deal with particular quartic Thue equations, where more information about the coefficients of the quartic form are available. Therefore, in applications, the strong condition on the size of discriminant may be removed.

The equation
\[
x^4 - 4x^3y - x^2y^2 + 4xy^3 + y^4 = 1
\]
has exactly 8 solutions \( (x, y) = (0, 1), (1, 0), (1, 1), (-1, 1), (4, 1), (-1, 4), (8, 7), (-7, 8) \) (see [11] for a proof). The author is not aware of any binary quartic forms \( F(x, y) \) for which the equation \( F(x, y) = 1 \) has more than 8 solutions. Magma [7] did not find any solution to
\[
x^4 - 4x^3y - x^2y^2 + 4xy^3 + y^4 = -1.
\]

We will always assume that \( F(x, y) \) is irreducible. In fact, when the form \( F(x, y) \) is not reducible over \( \mathbb{Z}[x, y] \), we are in a much simpler situation. In general, equation (1) may have infinitely many integral solutions; \( F(x, y) \) could, for instance, be a power of a linear or indefinite binary quadratic form that represents unity. If \( F(x, y) \) is not an irreducible form, however, we may very easily derive a stronger version of our main theorem under the assumption that \( F(x, y) \) is neither a 4th power of a linear form nor a second power of a quadratic form. Suppose that \( F(x, y) \) is reducible and can be factored over \( \mathbb{Z}[x, y] \) as follows
\[
F(x, y) = F_1(x, y)F_2(x, y),
\]
with \( \deg(F_1) \leq \deg(F_2) \) and \( F_1 \) irreducible over \( \mathbb{Z}[x, y] \). Therefore, the following equations must be satisfied:

\[
\begin{align*}
(2) & \quad F_1(x, y) = \pm 1 \\
(3) & \quad F_2(x, y) = \pm 1.
\end{align*}
\]

This means the number of solutions to (1) is no more than the minimum of number of solutions to (2) and (3). First suppose that \( F_1 \) is a linear form. Then the equation (3) can be written as a polynomial of degree 3 in \( x \) and therefore there are no more than 12 complex solutions to above equations. Now let us suppose that \( F_1 \) is a quadratic form. Using Bézout’s theorem from classical algebraic geometry concerning the number of common points of two plane algebraic curves, we conclude that (1) has at most 16 integral solutions.

In this manuscript, we give new and sharper bounds for the number of solutions to equation (1). The bound given in [2] is improved here mostly due to some adjustment in the definition of the logarithmic curve \( \phi(x, y) \) in Section 6. We also study the geometry of binary forms with respect to their signature to get amore precise understanding of the distribution of solutions to (1). We also appeal to a result of Voutier (Proposition 2.2) to estimate the height of algebraic numbers in the number field generated over \( \mathbb{Q} \) by a root of the equation \( F(x, 1) = 0 \). These allow us to extend our method introduced in [2] for quartic forms that split in \( \mathbb{R} \) to all quartic forms.
2. Preliminaries

Let $f(x) = a_n x^n + \ldots + a_1 x + a_0$ be the minimal polynomial of an algebraic number $\alpha \neq 0$. Suppose that over $\mathbb{C}$,

$$f(x) = a_n(x - \alpha_1) \ldots (x - \alpha_n).$$

We put

$$M(\alpha) = M(f) = |a_n| \prod_{i=1}^n \max(1, |\alpha_i|).$$

$M(\alpha)$ is known as the Mahler measure of $\alpha$.

The Mahler measure of a binary form $G(x, y)$ is defined to be equal to the Mahler measure of the polynomial $G(x, 1)$. In [8], Mahler showed, for polynomial $G$ of degree $n$ and discriminant $D_G$, that

$$(4) \quad M(G) \geq \left( \frac{D_G}{n^n} \right)^{\frac{1}{n-1}}.$$

Let $F(x, y)$ be a quartic form that factors over $\mathbb{C}$ as follows

$$F(x, y) = a_0(x - \alpha_1 y)(x - \alpha_2 y)(x - \alpha_3 y)(x - \alpha_4 y).$$

The discriminant $D$ of $F$ is given by

$$D = D_F = a_0^6(a_1 - a_2)^2(a_1 - a_3)^2(a_1 - a_4)^2(a_2 - a_3)^2(a_2 - a_4)^2(a_3 - a_4)^2.$$ We call forms $F$ and $G$ equivalent if they are equivalent under $GL_2(\mathbb{Z})$-action; i.e. if there exist integers $a_1, a_2, a_3$ and $a_4$ such that

$$F(a_1x + a_2y, a_3x + a_4y) = G(x, y)$$

for all $x, y$, where $a_1a_4 - a_2a_3 = \pm 1$. We denote by $N_F$ the number of solutions in integers $x$ and $y$ of the Diophantine equation (1). If $F$ and $G$ are equivalent then $N_F = N_G$ and $D_F = D_G$.

Suppose there is a solution $(x_0, y_0)$ to equation (1). Since

$$\gcd(x_0, y_0) = 1,$$

there exist integers $x_1, y_1 \in \mathbb{Z}$ with

$$x_0 y_1 - x_1 y_0 = 1.$$

Then

$$F^*(1, 0) = 1,$$

where

$$F^*(x, y) = F(x_0 x + x_1 y, y_0 x + y_1 y).$$

Therefore, $F^*$ is a monic form equivalent to $F$. From now on we will assume $F$ is monic.

Let $\mathbb{Q}(\alpha_1)^n$ be the embeddings of the real number field $\mathbb{Q}(\alpha_1)$ in $\mathbb{R}$, $1 \leq \sigma \leq n$, where $\{\alpha_1, \alpha_2, \ldots, \alpha_n\}$ are roots of $F(x, 1) = 0$. We respectively have $n$ Archimedean valuations of $\mathbb{Q}(\alpha_1)$:

$$|\rho|_\sigma = |\rho(\sigma)|, \quad 1 \leq \sigma \leq n.$$ We enumerate simple ideals of $\mathbb{Q}(\alpha)$ by indices $\sigma > n$ and define non-Archimedean valuation of $\mathbb{Q}(\alpha)$ by the formulas

$$|\rho|_\sigma = (\text{Norm } \mathfrak{p})^{-k},$$
where \[ k = \text{ord}_p(\alpha), \ p = p_\sigma, \ \sigma > n, \]
for any \( \rho \in \mathbb{Q}^*(\alpha) \). Then we have the product formula:
\[ \prod_{\sigma} |\rho|_\sigma = 1, \ \rho \in \mathbb{Q}(\alpha). \]
Note that \(|\rho|_\sigma \neq 1\) for only finitely many \( \rho \). We should also remark that if \( \sigma_2 = \bar{\sigma}_1 \), i.e., \( \sigma_2(x) = \bar{\sigma}_1(x) \) for \( x \in \mathbb{Q}(\alpha) \), then the valuations \( |.|_{\sigma_1} \) and \( |.|_{\sigma_2} \) are equal. We define the absolute logarithmic height of \( \rho \) as
\[ h(\rho) = \frac{1}{2n} \sum_{\sigma=1}^{\infty} |\log |\rho|_\sigma|. \]

**Proposition 2.1.** For every non-zero algebraic number \( \alpha \), we have \( h(\alpha^{-1}) = h(\alpha) \).
For algebraic numbers \( \alpha_1, \ldots, \alpha_n \), we have
\[ h(\alpha_1 \ldots \alpha_n) \leq h(\alpha_1) + \ldots + h(\alpha_n) \]
and
\[ h(\alpha_1 + \ldots + \alpha_n) \leq \log n + h(\alpha_1) + \ldots + h(\alpha_n). \]

**Proof.** See [4] for proof. \( \square \)

**Proposition 2.2.** (Voutier [17]) Suppose \( \alpha \) is a non-zero algebraic number of degree \( n \) which is not a root of unity. If \( n \geq 2 \) then
\[ h(\alpha) = \frac{1}{n} \log M(\alpha) > \frac{1}{4} \left( \frac{\log \log n}{\log n} \right)^3. \]

Let \( \alpha \) and \( \beta \) be two algebraic numbers. Then the following inequalities hold (see [4]):

(5) \[ h(\alpha + \beta) \leq \log 2 + h(\alpha) + h(\beta) \]
and

(6) \[ h(\alpha \beta) \leq h(\alpha) + h(\beta). \]

**Lemma 2.3.** (Mahler [8]) If \( a \) and \( b \) are distinct zeros of polynomial \( P(x) \) with degree \( n \), then we have
\[ |a - b| \geq \sqrt{3}(n)^{-(n+2)/2}M(P)^{-n+1}, \]
where \( M(P) \) is the Mahler measure of \( P \).

**Lemma 2.4.** Let \( f(x) = a_n x^n + \ldots + a_1 x + a_0 \) be an irreducible polynomial of degree \( n \) and \( \alpha_m \) be one of its roots. For \( f'(x) \) the derivative of \( f \), we have
\[ 2^{-(n-1)^2} \frac{|D_f|}{M(f)2^{n-2}} \leq |f'(\alpha_m)| \leq \frac{n(n+1)}{2} H(f) (\max(1, |\alpha_m|))^{n-1}, \]
where \( D_f \) is the discriminant, \( M(f) \) is the Mahler measure and \( H(f) \) is the naive height of \( f \).
Proof. The right hand side inequality is trivial by noticing that
\[ f'(x) = na_nx^{n-1} + \ldots + a_1x. \]
To see the left hand side inequality, observe that for \( \alpha_i, \alpha_j \), two distinct roots of \( f(x) \), we have
\[ |\alpha_i - \alpha_j| \leq 2 \max(1, |\alpha_i|) \max(1, |\alpha_j|). \]
Then
\[
|f'(\alpha_m)| = \prod_{i=1, i \neq m}^{n} |\alpha_i - \alpha_m| \geq \prod_{i=1, i \neq m}^{n} \frac{|\alpha_i - \alpha_m|}{\max(1, |\alpha_i|) \max(1, |\alpha_m|)} \\
\geq 2^{n-1-n(n-1)} \prod_{j=1}^{n} \prod_{i=1, i \neq j}^{n} \frac{|\alpha_i - \alpha_j|}{\max(1, |\alpha_i|) \max(1, |\alpha_j|)} \\
= 2^{-(n-1)^2} \frac{|D_F|}{M(F)^{2n-2}}.
\]
\[ \square \]

Suppose that \( K \) is an algebraic number field of degree \( d \) over \( \mathbb{Q} \) embedded in \( \mathbb{C} \). If \( K \subset \mathbb{R} \), we put \( \chi = 1 \), and otherwise \( \chi = 2 \). We are given numbers \( \alpha_1, \ldots, \alpha_n \in K^\times \) with absolute logarithm heights \( h(\alpha_j), 1 \leq j \leq n \). Let \( \log \alpha_1, \ldots, \log \alpha_n \) be arbitrary fixed non-zero values of the logarithms. Suppose that
\[ A_j \geq \max\{db(\alpha_j), |\log \alpha_j|\}, \ 1 \leq j \leq n. \]
Now consider the linear form
\[ L = b_1 \log \alpha_1 + \ldots + b_n \log \alpha_n, \]
with \( b_1, \ldots, b_n \in \mathbb{Z} \) and with the parameter
\[ B = \max\{1, \max\{b_jA_j/A_n : 1 \leq j \leq n\}\}. \]
For brevity we put
\[ \Omega = A_1 \ldots A_n, \]
\[ C(n) = C(n, \chi) = \frac{16}{n!\chi} e^n (2n + 1 + 2\chi)(n + 2)(4n + 4)^{n+1} \left( \frac{1}{2en} \right)^\chi, \]
\[ C_0 = \log(e^{4.4n+7}n^{5.5}d^2 \log(en)), \]
\[ W_0 = \log(1.5eBd \log(ed)). \]
The following is the main result of [10].

**Proposition 2.5 (Matveev).** If \( \log \alpha_1, \ldots, \log \alpha_n \) are linearly independent over \( \mathbb{Z} \) and \( b_n \neq 0 \), then
\[ \log |L| > -C(n)C_0W_0d^2\Omega. \]
3. SUMMARY OF THE PROOF

Suppose that \((x, y)\) is an integral solution to equation (1). Then we have
\[
(x - \alpha_1 y)(x - \alpha_2 y)(x - \alpha_3 y)(x - \alpha_4 y) = \pm 1.
\]
Therefore, for some \(1 \leq i \leq 4\),
\[
|x - \alpha_i y| \leq 1.
\]

**Definition.** We say the pair of solution \((x, y)\) is related to \(\alpha_i\) if
\[
|x - \alpha_i y| = \min_{1 \leq j \leq 4} |x - \alpha_j y|.
\]

**Proposition 3.1.** Let \(F(x, y)\) be an irreducible monic binary quartic form with integer coefficients and Mahler measure \(M(F)\). The Diophantine equation (1) has at most \(N_1\) (see the table below) solutions in integers \(x\) and \(y\) with \(0 < y < M(F)^{3.5}\), provided that the discriminant of \(F\) is greater than \(D_0\), where \(D_0\) is an explicitly computable constant.

Since \(F(x, y)\) is monic, \((1, 0)\) is a trivial solution to \(F(x, y) = 1\). We will need to define a subset of solutions to (1), called \(A\) (see Section 8 for details). This set contains the trivial solution \((1, 0)\) and 5 other pairs of solution only when \(F(x, 1) = 0\) has 4 real roots.

4. Solutions with small $y$; the Proof of Proposition 3.1

We may suppose that $F(x, y)$ is a monic form and has the smallest Mahler measure among all monic forms that are equivalent to $F$. Assume that $F(x, 1) = 0$ has $r$ real roots and $2s$ non-real roots ($r + 2s = 4$).

Let $Y_0$ be a positive real number. Following Stewart [16] and Bombieri and Schmidt [3], we will estimate the solutions $(x, y)$ to (1) for which $0 < y \leq Y_0$. For binary form

$$F(x, y) = (x - \alpha_1 y) \ldots (x - \alpha_n y)$$

put $L_i(x, y) = x - \alpha_i y$ for $i = 1, \ldots, n$.

Lemma 4.1. Suppose $F$ is a monic binary form. Then for every solutions $(x, y)$ of (1) we have

$$\frac{1}{L_i(x, y)} - \frac{1}{L_j(x, y)} = (\beta_j - \beta_i)y,$$

where $\beta_1, \ldots, \beta_n$ are such that the form

$$J(u, w) = (u - \beta_1 w) \ldots (u - \beta_n w)$$

is equivalent to $F$.

Proof. This is Lemma 4 of [16] and Lemma 3 of [3], by taking $(x_0, y_0)$ equal to $(1, 0)$. \hfill $\square$

For every solution $(x, y) \neq (1, 0)$ of (1), fix $j = j(x, y)$ with $|L_j(x, y)| \geq 1.$

Then, by Lemma 4.1,

$$\frac{1}{|L_i(x, y)|} \geq |\beta_j - \beta_i||y| - 1.$$  \hfill (7)

For complex conjugate $\bar{\beta}_j$ of $\beta_j$, where $j = j(x, y)$, we also have

$$\frac{1}{|L_i(x, y)|} \geq |\bar{\beta}_j - \beta_i||y| - 1.$$  \hfill (8)

Hence

$$\frac{1}{|L_i(x, y)|} \geq |\text{Re}(\beta_j) - \beta_i||y| - 1,$$

where $\text{Re}(\beta_j)$ is the real part of $\beta_j$. We now choose an integer $m = m(x, y)$ with $|\text{Re}(\beta_j) - \beta_j| \leq 1/2$, and we obtain

$$\frac{1}{|L_i(x, y)|} \geq \left( |m - \beta_i| - \frac{1}{2} \right) |y| - 1,$$

for $i = 1, \ldots, n$.

Definition. For $1 \leq i \leq n$, let $\mathcal{X}_i$ be the set of solutions to (1) with $1 \leq y \leq Y_0$ and $|L_i(x, y)| \leq \frac{1}{2y}$.

Remark. When $\alpha_k$ and $\alpha_l$ are complex conjugates, $\mathcal{X}_l = \mathcal{X}_k$ and therefore we only need to consider $r + s$ different sets $\mathcal{X}_i$. 
Lemma 4.2. Suppose \((x_1, y_1)\) and \((x_2, y_2)\) are two distinct solutions in \(\mathfrak{X}_i\) with \(y_1 \leq y_2\). Then
\[
\frac{y_2}{y_1} \geq \frac{2}{7} \max(1, |\beta_i(x_1, y_1) - m(x_1, y_1)|).
\]

Proof. This is Lemma 5 of [16] and Lemma 4 of [3]. \(\square\)

Lemma 4.3. Suppose \((x, y)\) is a solution to (1) with \(y > 0\) and \(|L_i(x, y)| > \frac{1}{2y}\). Then
\[
|m(x, y) - \beta_i(x, y)| \leq \frac{7}{2}.
\]

Proof. This is Lemma 6 of [16]. \(\square\)

By Lemma 4.1 the form
\[
J(u, w) = (u - \beta_1 w) \ldots (u - \beta_n w)
\]
is equivalent to \(F(x, y)\) and therefore the form
\[
\hat{J}(u, w) = (u - (\beta_1 - m) w) \ldots (u - (\beta_n - m) w)
\]
is also equivalent to \(F(x, y)\). Therefore, since we assumed that \(F\) has the smallest Mahler measure among its equivalent forms, we get
\[
\prod_{i=1}^{n} \max(1, |\beta_i(x, y) - m(x, y)|) \geq M(F).
\]

For each set \(\mathfrak{X}_i\) that is not empty, let \((x^{(i)}, y^{(i)})\) be the element with the largest value of \(y\). Let \(\mathfrak{X}\) be the set of solutions of (1) with \(1 \leq y \leq Y_0\) minus the elements \((x^{(1)}, y^{(1)}), \ldots, (x^{(r+s)}, y^{(r+s)})\). Suppose that, for integer \(i\), the set \(\mathfrak{X}_i\) is non-empty. Index the elements of \(\mathfrak{X}_i\) as
\[
(x^{(i)}, y^{(i)}), \ldots, (x^{(v)}, y^{(v)}),
\]
so that \(y^{(i)}_1 \leq \ldots \leq y^{(i)}_v\) (note that \((x^{(i)}, y^{(i)}) = (x^{(i)}, y^{(i)})\)). By Lemma 4.2
\[
\frac{2}{7} \max \left(1, \left|\beta_i(x^{(i)}_k, y^{(i)}_k)\right|\right) \leq \frac{y^{(i)}_{k+1}}{y^{(i)}_k}
\]
for \(k = 1, \ldots, v - 1\). Hence
\[
\prod_{(x, y) \in \mathfrak{X} \cap \mathfrak{X}_i} \frac{2}{7} \max \left(1, \left|\beta_i(x^{(i)}_k, y^{(i)}_k)\right|\right) \leq Y_0.
\]

For \((x, y)\) in \(\mathfrak{X}\) but not in \(\mathfrak{X}_i\) we have
\[
\frac{2}{7} \max \left(1, \left|\beta_i(x^{(i)}_k, y^{(i)}_k)\right|\right) \leq 1.
\]

By Lemma 4.3. Thus
\[
\prod_{(x, y) \in \mathfrak{X}} \frac{2}{7} \max \left(1, \left|\beta_i(x^{(i)}_k, y^{(i)}_k)\right|\right) \leq Y_0.
\]

Comparing this with (9) and since we have at most \(r + s\) different sets \(\mathfrak{X}_i\), we obtain
\[
\left(\frac{2}{7}\right)^4 M(F)^{|\mathfrak{X}|} \leq Y_0^{r+s}.
\]
If $D_F$ satisfies the following numerical inequality
\[ D_F \geq 4^4 \left( \frac{7}{2} \right)^{4 \times 6 \times 65} \]
then we have
\[ \left( \frac{D_F}{4^4} \right)^{\frac{1}{7^{\frac{1}{4}}}} \geq \left( \frac{7}{2} \right)^4. \]
From here and the fact that $M(F) \geq \left( \frac{D_F}{4^4} \right)^{\frac{1}{7^{\frac{1}{4}}}}$ (see (4)), we conclude that if the discriminant is large enough then $M(F)$ will be large enough to satisfy
\[ \left( \frac{2}{7} \right)^4 M(F) \geq M(F)^{\frac{64}{65}}. \]
By (10),
\[ (11) \quad |X| < (r + s) \frac{65 \log Y_0}{64 \log M(F)}. \]
When $F(x, y)$ has signature (4, 0), choose $\theta_1 > 0$ such that
\[ \frac{65}{16} \left( \frac{11}{6} + \theta_1 \right) < 8. \]
From (10), we conclude that in this case $|X|$ is at most 7 and therefore (1) has at most 11 solutions with $1 \leq y < M(f)^{\frac{11}{6}_+ + \theta_1}$. When $F(x, y)$ has signature (2, 1) choose $\theta_2 > 0$ such that
\[ 3 \times \frac{65}{64} \left( \frac{11}{6} + \theta_2 \right) < 6. \]
From (10), we conclude that in this case $|X|$ is at most 5 and therefore (1) has at most 8 solutions with $1 \leq y < M(f)^{\frac{11}{6}_+ + \theta_2}$. We can repeat the similar argument for forms with signature (0, 2) and choose $\theta_3 > 0$ such that
\[ 2 \times \frac{65}{64} \left( \frac{11}{6} + \theta_3 \right) < 4. \]
This will give us at most 5 solutions with $1 \leq y < M(f)^{\frac{11}{6}_+ + \theta_3}$. But for this case, we have more to say in the next section.

Lemma 4.4. Let $F$ be a binary form of degree $n \geq 3$ with integer coefficients and nonzero discriminant $D$. For every pair of integers $(x, y)$ with $y \neq 0$
\[ \min_{\alpha} \left| \alpha - \frac{x}{y} \right| \leq \frac{2^{n-1}n^{n-1/2}(M(F))^{n-2}|F(x, y)|}{|D(F)|^{1/2}|y|^n}, \]
where the minimum is taken over the zeros $\alpha$ of $F(z, 1)$.

Proof. This is Lemma 3 of [16].

Lemma 4.5. Let $F(x, y)$ be a quartic binary form with discriminant $D$, where $|D| \geq D_0$. Suppose that $\alpha_i$ is a root of $F(z, 1) = 0$. Suppose that $\theta > 0$. Then related to $\alpha_i$, there is at most 1 solution for equation (1) in integers $x$ and $y$ with
\[ \left( \frac{11}{6} + \theta \right) < y < M(F)^{3.5}. \]
**Proof.** Assume that \((x_1, y_1)\) and \((x_2, y_2)\) are two distinct solutions to (1), both related to \(\alpha_i\) with \(y_2 > y_1 > M(F)^2\). By Lemma 4.4, we have

\[
\left| x_2 - \frac{x_1}{y_1} \right| = \left| \alpha_i - \frac{x_1}{y_1} \right| \leq \frac{2^{3 \cdot 7/2} (M(F))^2}{|D(F)|^{1/2} |y_1|^{1/4}} + \frac{2^{3 \cdot 7/2} (M(F))^2}{|D(F)|^{1/2} |y_2|^{1/4}}.
\]

Since \((x_1, y_1)\), \((x_2, y_2)\) are distinct, we have \(|x_2 y_1 - x_1 y_2| \geq 1\). Therefore,

\[
\left| \frac{x_2}{y_2} - \frac{x_1}{y_1} \right| \leq \frac{M(F)^2}{|y_1|^2}.
\]

This is because we assumed that \(D_F\) is large. Thus,

\[
y_2^3 / M(F)^2 \leq y_2.
\]

Following Stewart [16], we define \(\delta_j\), for \(j = 1, 2\), by

\[
y_j = M(F)^{1+\delta_j}.
\]

By (4) the Mahler measure of \(F\) is large and (12) implies that

\[
3\delta_1 \leq \delta_2.
\]

From here, we conclude that

\[
y_2 > M(F)^{3.5}.
\]

In other words, related to each root \(\alpha_i\), there exists at most 1 solution in \(x\) and \(y\) with \(M(F)^{12 + \theta_1} < y < M(F)^{3.5}\). \(\square\)

5. **Proof of the Main Theorem for Forms with signature \(0, 2\)**

We will first show that if a pair of integer \((x, y)\) satisfies \(F(x, y) = \pm 1\) and is related to a non-real root \(\alpha\) of \(F(x, 1) = 0\) then

\[
|y| < M(F)^{9/4}.
\]

**Lemma 5.1.** For quartic binary form \(F(x, y)\), let \(\alpha\) be a non-real root of \(F(x, 1) = 0\). If a pair of integer \((x, y)\) satisfies \(F(x, y) = \pm 1\) and is related to \(\alpha\) then

\[
|y| \leq 2^{19} (\sqrt[14]{|D_F|}) \frac{M(F)^{9/4}}{2^{14}}.
\]

**Proof.** Let \(\alpha = x + it\), with \(t \neq 0\), be a non-real root of \(F(x, 1) = 0\). If a solution \((x, y)\) of (1) is related to \(\alpha\) then \(\bar{\alpha}\), the complex conjugate of \(\alpha\), is also a root of \(F(x, 1) = 0\) and we have

\[
\left| \frac{x}{y} - \alpha \right| = \left| \frac{z}{y} - \alpha \right| + \left| \frac{\bar{z}}{y} - \bar{\alpha} \right| \geq \frac{|\alpha - \bar{\alpha}|}{2}.
\]

Moreover, if \(\beta \neq \alpha\) is a root of \(F(x, 1) = 0\) then

\[
\left| \frac{x}{y} - \beta \right| \geq \left| \frac{z}{y} - \alpha \right| + \left| \frac{\bar{z}}{y} - \beta \right| \geq \frac{|\beta - \alpha|}{2}.
\]
Thus
\[
\frac{1}{|y|^4} = \frac{|x - \alpha|}{|y|} \prod_{\alpha_i \neq \alpha} \frac{|x - \alpha_i|}{|y|} \\
\geq \frac{|\alpha - \bar{\alpha}|}{2} \prod_{\alpha_i \neq \alpha} \frac{|\alpha - \alpha_i|}{2} \\
= |\alpha - \bar{\alpha}| |f'(\alpha)| 2^{-4}.
\]

By Lemma 2.3,
\[|\alpha - \bar{\alpha}| \geq \sqrt{3} \cdot 3 - 3 M(F) - 3.\]
This, together with Lemma 2.4, shows that
\[\frac{1}{|y|^4} \geq \sqrt{32} - 19 |D_F| M(F)^{-3/4}.\]
This completes our proof.

Suppose that \((x_1, y_1)\) and \((x_2, y_2)\) are two solutions related to a fixed root \(\alpha\), with \(M(F)^{17/4 + \theta_3} < y_1 < y_2 < M(F)^{9/4}\). Similar to the proof of Lemma 4.5, we define \(\delta_j\), for \(j = 1, 2\), by
\[y_j = M(F)^{1 + \delta_j}.\]
Inequality (12) implies that
\[3\delta_1 \leq \delta_2.\]
From here, we conclude that if \(y_1 \geq M(F)^{17/4 + \theta_3}\) then
\[y_2 \geq M(F)^{9/4}.\]
In other words, related to each root \(\alpha_i\), there exists at most 1 solution in \(x\) and \(y\) with \(M(F)^{17/4 + \theta_3} < y < M(F)^{9/4}\).

When \(F(x, y)\) has signature \((0, 2)\) Choose \(\theta_3 > 0\) such that
\[2 \times \frac{65}{64} \left(\frac{17}{12} + \theta_3\right) < 3.\]
From (10), we conclude that in this case \(|\mathcal{X}|\) is at most 2 and therefore (1) has at most 4 solutions with \(1 \leq y < M(f)^{17/4 + \theta_3}\).

Since \(F\) is monic, \((1, 0)\) is a trivial solution to equation (1). Therefore, when \(F\) has signature \((0, 2)\) the number of solutions to (1) does not exceed 6.

6. Transcendental Curve \(\phi(x, y)\)

Fix a positive integer \(k\). Define
\[
\phi_m(x, y) = \log \frac{D_f^\frac{k}{2} (x - y\alpha_m)}{|f'(\alpha_m)|^\frac{k}{2}}
\]
and
\[
\phi(x, y) = (\phi_1(x, y), \phi_2(x, y), \phi_3(x, y), \phi_4(x, y)).
\]
Let \(\|\phi(x, y)\|\) be the \(L_2\) norm of the vector \(\phi(x, y)\).

Remark. In [2], a logarithmic curve \(\phi(x, y)\) is defined by taking \(k = 3\). The new general definition of \(\phi(x, y)\) in this paper gives us the freedom of choosing \(k\)
large enough to make our approximations sharper. In order to have our estimations correct it is sufficient to take $k = 90$.

**Lemma 6.1.** Suppose that $(x, y)$ is a solution to the equation $F(x, y) = 1$, where $F$ is the binary form in Theorem 1.1. If

$$|x - \alpha_i y| = \min_{1 \leq j \leq 4} |x - \alpha_j y|$$

then

$$\|\phi(x, y)\| \leq 6 \log \frac{1}{|x - \alpha_i y|} + \|\phi(1, 0)\|.$$ 

**Proof.** Let us assume that

$$|x - \alpha_{s_j} y| < 1, \quad \text{for } 1 \leq j \leq p$$

and

$$|x - \alpha_{b_k} y| \geq 1, \quad \text{for } 1 \leq k \leq 4 - p,$$

where $1 \leq p, s_j, b_k \leq 4$. We have

$$\prod_k |x - \alpha_{b_k} y| = \frac{1}{\prod_j |x - \alpha_{s_j} y|}.$$ 

Therefore, for any $1 \leq k \leq 4 - p$, we have

$$\log |x - \alpha_{b_k} y| \leq p \log \frac{1}{|x - \alpha_i y|}.$$ 

Since

$$|x - \alpha_i y| = \min_{1 \leq j \leq 4} |x - \alpha_j y|,$$

we also have

$$\log |x - \alpha_{s_j} y| \leq |\log |x - \alpha_i y||.$$ 

From here, we conclude that

$$\|\phi(x, y)\| \leq \|\phi(1, 0)\| + (4 - p)p |\log |x - \alpha_i y|| + p |\log |x - \alpha_i y||$$

$$= \|\phi(1, 0)\| + (5p - p^2) |\log |x - \alpha_i y||.$$ 

The function $A(p) = 5p - p^2$ obtains its maximum value 6 over $p \in \{1, 2, 3, 4\}$. \hfill \Box

In the following lemma we approximate the size of $f'(\alpha)$ in terms of the discriminant and heights of $f$, where $f'$ is the derivative of the polynomial $f$ and $\alpha$ is a root of $f = 0$.

**Lemma 6.2.** Suppose that $F$ is a monic quartic binary form. Then $(1, 0)$ is a solution to the equation $|F(x, y)| = 1$ and

$$\|\phi(1, 0)\| \leq 4 \log \left(\frac{2^9}{k} D^\frac{3}{2} M(F)^\frac{2}{3}\right),$$

**Proof.** By the definition of $\phi(x, y)$,

$$\|\phi(1, 0)\| \leq \sum_{m=1}^{4} \log \left|\frac{D^\frac{1}{2} M(F)^\frac{2}{3}}{|f'(\alpha_m)|^\frac{1}{2}}\right|$$

Substituting the lower bound for the $|f'(\alpha_m)|^\frac{1}{2}$ from Lemma 2.4 completes the proof. \hfill \Box
7. Exponential Gap Principle

Here, our goal is to show

**Proposition 7.1.** Suppose that \((x_1, y_1), (x_2, y_2)\) and \((x_3, y_3)\) are three pairs of non-trivial solutions to (1) with

\[|x_j - \alpha_4 y_j| < 1,\]

and \(|y_j| > M(F)^{3.5}, \text{ for } j \in \{1, 2, 3\}.\] If \(\|\phi(x_1, y_1)\| \leq \|\phi(x_2, y_2)\| \leq \|\phi(x_3, y_3)\|\) then

\[\|\phi(x_3, y_3)\| > 0.00014 \exp \left( \frac{\|\phi(x_1, y_1)\|}{6} \right).\]

In [2], we showed that when \(F(x, y)\) splits in \(\mathbb{R}\), i.e. when the signature is \((4, 0)\), assuming that \(y_3 > y_1 > M(F)^6\), one can get the following inequality

\[\|\phi(x_3, y_3)\| > \exp \left( \frac{\|\phi(x_1, y_1)\|}{6} \right) 2 \sqrt{3} \log^4 \frac{1 + \sqrt{7}}{2},\]

that is sharper than the inequality in Proposition 7.1. This makes the value of \(D_0\) in our main theorem smaller and does not decrease the upper bound for the number of solutions.

Observe that for three pairs of solutions in Proposition 7.1, the three points \(\phi(x_1, y_1), \phi(x_2, y_2)\) and \(\phi(x_3, y_3)\) form a triangle \(\Delta\). To establish Proposition 7.1, we will find a lower bound and an upper bound for the area of \(\Delta\). Then comparing these bounds, Proposition 7.1 will be proven. The length of each side of \(\Delta\) is less than \(2 \|\phi(x_3, y_3)\|\). Lemma 7.2 gives an upper bound for the height of \(\Delta\). Let \((x, y) \neq (1, 0)\) be a solution to (1) and let \(t = \frac{x}{y}\). We have

\[\phi(x, y) = \phi(t) = \sum_{i=1}^{4} \log \frac{|t - \alpha_i|}{|f'(\alpha_i)|^{\frac{1}{2}}} b_i,\]

where,

\[b_1 = \frac{1}{4}(3, -1, -1, -1), \quad b_2 = \frac{1}{4}(-1, 3, -1, -1),\]

\[b_3 = \frac{1}{4}(-1, -1, 3, -1), \quad b_4 = \frac{1}{4}(-1, -1, -1, 3),\]

Without loss of generality, we will assume that \(\alpha_4\) is a real root and for the pair of solution \((x, y)\) we have

\[|x - \alpha_4 y| \leq 1.\]

We may write (see the definition of \(\phi(x, y)\) in (15))

\[\phi(x, y) = \phi(t) = \sum_{i=1}^{3} \log \frac{|t - \alpha_i|}{|f'(\alpha_i)|^{\frac{1}{2}}} c_i + E_4 b_4,\]

where, for \(1 \leq i \leq 3,\)

\[c_i = b_i + \frac{1}{3} b_4, \quad E_4 = \log \frac{|t - \alpha_4|}{|f'(\alpha_4)|^{\frac{1}{2}}} - \frac{1}{3} \sum_{i=1}^{3} \log \frac{|t - \alpha_i|}{|f'(\alpha_i)|^{\frac{1}{2}}} \]

One can easily observe that

\[c_i \perp b_4, \text{ for } 1 \leq i \leq 4.\]
Lemma 7.2. Let
\[ L_4 = \sum_{i=1}^{3} \log \frac{|\alpha_i - \alpha_4|}{|f'(\alpha_i)|^{\frac{1}{2}}} c_i + z b_4, \quad z \in \mathbb{R}. \]
Suppose that \((x, y) \neq (1, 0)\) is a pair of solution to (1) with
\[ |x - \alpha_4 y| = \min_{1 \leq j \leq 4} |x - \alpha_j y| \]
and \(y \geq M(F)^{3.5}\). Then the distance between \(\phi(x, y)\) and the line \(L_4\) is less than
\[ \exp \left( -\frac{\|\phi(x, y)\|}{6} \right). \]

Proof. The proof goes exactly as the proof of Lemma 6.3 in [2].

Lemma 7.2 shows that the height of \(\Delta\) is at most
\[ 2 \exp \left( -\frac{\|\phi(x_1, y_1)\|}{6} \right). \]
Therefore, the area of \(\Delta\) is less than
\[ (17) \quad 2 \|\phi(x_3, y_3)\| \exp \left( -\frac{\|\phi(x_1, y_1)\|}{6} \right). \]

Let us now estimate the area of \(\Delta\) from below. Since
\[ F(x, y) = (x - \alpha_1 y)(x - \alpha_2 y)(x - \alpha_3 y)(x - \alpha_4 y) = \pm 1, \]
we conclude that \(x - \alpha_i y\) is a unit in \(\mathbb{Q}(\alpha_i)\) when \((x, y)\) is a pair of solution to (1). Suppose that \((x_1, y_1)\) and \((x_2, y_2)\) are two pairs of non-trivial solutions to (1). Then
\[ \phi(x_1, y_1) - \phi(x_2, y_2) = \left( \log \frac{x_1 - \alpha_1 y}{x_2 - \alpha_1 y}, \ldots, \log \frac{x_1 - \alpha_4 y}{x_2 - \alpha_4 y} \right) = \vec{e}. \]
Since \(\frac{x_1 - \alpha_i y}{x_2 - \alpha_i y}\) is a unit in \(\mathbb{Q}(\alpha_i)\), by Proposition 2.2, we have
\[ \|\vec{e}\| = 8 h \left( \frac{x_1 - \alpha_i y}{x_2 - \alpha_i y} \right) > 2 \left( \frac{\log \log 4}{\log 4} \right)^3 > 0.026. \]
Now we can estimate each side of \(\Delta\) from below to conclude that the area of the triangle \(\Delta\) is greater than
\[ \sqrt{3} \left( \frac{\log \log 4}{\log 4} \right)^6 > 0.00029. \]
Comparing this with (17) we conclude that
\[ 2 \|\phi(x_3, y_3)\| \exp \left( -\frac{\|\phi(x_1, y_1)\|}{6} \right) > 0.00029. \]
Proposition 7.1 is immediate from here.

Note that when \(\mathbb{Q}(\alpha_i)\) is a totally real field, we have a better upper bound for the size of \(\vec{e}\):
\[ \|\vec{e}\| \geq 4 \log^2 \frac{1 + \sqrt{5}}{2} \]
(see exercise 2 on page 367 of [14]). Now we can estimate each side of \(\Delta\) from below by
\[ 4 \sqrt{3} \log^4 \frac{1 + \sqrt{5}}{2}. \]
In order to study the curve $\phi(t)$, we will consider some well-known geometric properties of the unit group $U$ of $K = \mathbb{Q}(\alpha)$, where $\alpha$ is a root of $F(x, 1) = 0$. Let $r$ be the number of real conjugate fields of $K$ and $2s$ the number of complex conjugate fields of $K$. Then by Dirichlet’s unit theorem, the ring of integers $O_K$ contains $r + s - 1$ fundamental units and there are three possibilities:

- If $F(\alpha, 1) = 0$ has no real roots, we call $F$ a form of signature $(0, 2)$.
- If $F(\alpha, 1) = 0$ has 4 real roots, we call $F$ a form of signature $(4, 0)$.
- If $F(\alpha, 1) = 0$ has 2 real roots, we call $F$ a form of signature $(2, 1)$.

Here we are working with quartic forms ($r + 2s = 4$) we have $r + s - 1 = \frac{r}{2} + 1$ fundamental units in $O_K$. Let $\tau$ be the obvious restriction of the embedding of $\mathbb{Q}(\alpha)$ in $\mathbb{C}^4$; i.e. $\tau(u) = (u_1, u_2, u_3, u_4)$, where $u_i$ are algebraic conjugates of $u$. By Dirichlet’s unit theorem, we have a sequence of mappings

\begin{equation}
\tau : U \rightarrow V \subset \mathbb{C}^4
\end{equation}

and

\begin{equation}
\log : V \rightarrow \Lambda,
\end{equation}

where $V$ is the image of the map $\tau$, $\Lambda$ is a $r + s - 1$-dimensional lattice, and the mapping $\log$ is defined as follows:

For $(x_1, \ldots, x_{r+s-1}) \in V$,

$$
\log(x_1, \ldots, x_{r+s-1}) = (\log |x_1|, \ldots, \log |x_{r+s-1}|),
$$

where $r$ and $s$ are defined in Dirichlet’s unit Theorem. We have $r + s - 1 \leq 3$. If $(x, y)$ is a pair of solutions to (1) then

$$(x - \alpha_j y)$$

is a unit in $\mathbb{Q}(\alpha_i)$. Suppose that $\mathbb{Q}(\alpha_i)$ is a real number field and

$$
\lambda_2, \ldots, \lambda_{r+s}
$$

are fundamental units of $\mathbb{Q}(\alpha_i)$ and are chosen so that

$$
\log (\tau(\lambda_2)), \ldots, \log (\tau(\lambda_{r+s}))
$$

are respectively first to $r + s - 1$ successive minimas of the lattice $\Lambda$. Let us assume that

$$
\|\log (\tau(\lambda_2))\| \leq \ldots \leq \|\log (\tau(\lambda_{r+s}))\|
$$

form a reduced basis for the lattice $\Lambda$, so that

\begin{equation}
\phi(x, y) = \phi(1, 0) + \sum_{k=2}^{r+s} m_k \log (\tau(\lambda_k)), \quad m_k \in \mathbb{Z},
\end{equation}

with

\begin{equation}
\|m_k \log (\tau(\lambda_k))\| \leq \|\phi(x, y) - \phi(1, 0)\|.
\end{equation}
8. Geometry of $\phi(x, y)$

**Lemma 8.1.** For every fixed integer $m$, there are at most $2r + 2s - 2$ solutions $(x, y)$ to (1) for which in (20), $m_{r+s} = m$.

**Proof.** Let $S$ be the $(r + s - 1)$-dimensional affine space of all vectors

$$\phi(1, 0) + \sum_{i=2}^{r+s-1} \mu_i \log(\tau(\lambda_i)) (\mu_i \in \mathbb{R}).$$

Let $\mu_{r+s} = m$. Then the points

$$\phi(1, 0) + \sum_{i=2}^{r+s} \mu_i \log(\tau(\lambda_i)) + m \log(\tau(\lambda_{r+s}))$$

form an $(r + s - 2)$-dimensional hyperplane $S_1$ of $S$. Put $f(t) = F(t, 1)$. For $t \in \mathbb{R}$, define $y(t)$ and $x(t)$ as follows:

$$y(t) := |f(t)|^{-1/4},$$
$$x(t) := ty(t).$$

Similar to $\phi(x, y)$, we define the curve $\phi(t)$ on $\mathbb{R}$:

$$\phi(t) = (\phi_1(t), \phi_2(t), \phi_3(t), \phi_4(t)),$$

where, for $1 \leq m \leq 4$

$$\phi_m(t) = \log\left| \frac{D_i^k(x(t) - \alpha_m y(t))}{|f'(\alpha_m)|^k} \right|.$$

Observe that for an integral solution $(x, y)$ to (1) and $\phi(x, y)$ defined in (15), we have

$$\phi(x, y) = \phi\left(\begin{array}{c} x \\ y \end{array}\right).$$

Let $\vec{N} = (N_1, N_2, N_3, N_4) \in S$ be the normal vector of $S_1$. Then the number of times that the curve $\phi(t)$ intersects $S_1$ equals the number of solutions in $t$ to

(22)

$$\vec{N} \cdot \phi(t) = 0.$$

We have

$$\lim_{t \to \alpha_i^-} \log |t - \alpha_i| = -\infty$$

and

$$\lim_{t \to \alpha_i^+} \log |t - \alpha_i| = -\infty.$$

Note that if $\alpha_i$ is a non-real root of $F(x, 1)$ then $\tilde{\alpha}_i$, the complex conjugate of $\alpha_i$ is also a root and we have

$$\log |t - \alpha_i| = \log |t - \tilde{\alpha}_i|.$$  

If $\alpha_1, \ldots, \alpha_r$ are the reals roots and $\alpha_{r+1}, \ldots, \alpha_{r+s}, \alpha_{r+s+1}, \ldots, \alpha_{r+2s}$ are non-real roots with $\alpha_{r+s+k} = \tilde{\alpha}_{r+k}$, then the derivative

$$\frac{d}{dt} \left( \vec{N} \cdot \phi(t) \right)$$

can be written as $\frac{P(t)}{Q(t)}$, where $Q(t) = (t - \alpha_1) \ldots (t - \alpha_r)(t - \alpha_{r+1})(t - \alpha_{r+s})$ and $P(t)$ is a polynomial of degree $r + s - 1$. Therefore, the derivative has at most $r + s - 1$ zeros and consequently, the equation (22) can not have more than $2r + 2s - 2$ solutions.  \(\blacksquare\)
Lemma 8.2. Let $F$ be an irreducible monic quartic form. Suppose that $(x, y)$ is a solution to the Thue equation $F(x, y) = \pm 1$ with $y \geq M(F)^{3.5}$. Then
\[ \|\phi(1, 0)\| < \|\phi(x, y)\|. \]

Proof. Let $\alpha_1, \ldots, \alpha_n$ be the roots of $F(z, 1) = 0$. Then
\[ \left( \frac{x}{y} - \alpha_1 \right) \left( \frac{x}{y} - \alpha_2 \right) \left( \frac{x}{y} - \alpha_3 \right) \left( \frac{x}{y} - \alpha_4 \right) = \pm \frac{1}{y^4}. \]

There must exist a root $\alpha_j$ so that $\left| \frac{x}{y} - \alpha_j \right| \geq \frac{1}{y}$. By Lemma 2.4 and since $y \geq M(F)^{3.5}$, the absolute value of the term $\phi_j(x, y)$ alone exceeds $\|\phi(1, 0)\|$ (see Lemma 6.2).

Recall that we assumed $F(x, y)$ is a monic form. Therefore $(1, 0)$ is a trivial solution to the equation $F(x, y) = \pm 1$.

Definition of the set $\mathfrak{A}$. Assume that equation (1) has more than $2r + 2s - 2$ solutions. Then we can list $2r + 2s - 3$ solutions $(x_i, y_i) \neq (1, 0)$ $(1 \leq i \leq 2r + 2s - 3)$, so that $r_i = \|\phi(x_i, y_i)\|$ are the smallest among all $\|\phi(x, y)\|$, where $(x, y)$ varies over all non-trivial pairs of solutions. We denote the set of all these $2r + 2s - 3$ solutions and the trivial solution $(1, 0)$ by $\mathfrak{A}$.

Corollary 8.3. Let $(x, y) \notin \mathfrak{A}$ be a solution to (1) with $y > M(F)^{3.5}$. Then
\[ \|\log (\tau(\lambda_2))\| \leq \ldots \leq \|\log (\tau(\lambda_{r+s}))\| \leq 2 \|\phi(x, y)\|. \]

Proof. Since we have assumed that $\|\log (\tau(\lambda_2))\| \leq \ldots \leq \|\log (\tau(\lambda_{r+s}))\|$, it is enough to show that $\|\log (\tau(\lambda_{r+s}))\| \leq 2 \|\phi(x, y)\|$. By Lemma 8.1, there is at least one solution $(x_0, y_0) \in \mathfrak{A}$ so that
\[ \phi(x, y) - \phi(x_0, y_0) = \sum_{i=2}^{r+s} k_i \log (\tau(\lambda_i)), \]
with $k_n \neq 0$. Since $\{\log (\tau(\lambda_i))\}$ is a reduced basis for the lattice $\Lambda$ in (19), we conclude that
\[ \|\log (\tau(\lambda_{r+s}))\| \leq \|\phi(x, y) - \phi(x_0, y_0)\| \leq 2 \|\phi(x, y)\|. \]

Lemma 8.4. Suppose that $(x, y)$ is a solution to (1) with $y \geq M(F)^{3.5}$. We have
\[ \|\phi(x, y)\| \geq \frac{1}{2} \log \left( \frac{|D|^{1/12}}{2} \right). \]

Proof. Let $\alpha_i$ and $\alpha_j$ be two distinct roots of quartic polynomial $F(x, 1)$. We have
\[
\left| e^{\phi(1, 0)} - \phi_i(x, y) - e^{\phi(1, 0)} - \phi_j(x, y) \right| = \left| \frac{1}{x - y\alpha_i} - \frac{1}{x - y\alpha_j} \right| \geq \frac{|\alpha_i - \alpha_j|}{|x - y\alpha_i||x - y\alpha_j|}.
\]

...
Since $|\phi_i| < \|\phi\|$ and $\|\phi(1, 0)\| \leq \|\phi(x, y)\|$, we may conclude
\[
\left(2e^{2\|\phi(x,y)\|}\right)^6 \geq \prod_{1 \leq i < j \leq 4} \left|\frac{1}{x - ya_i} - \frac{1}{x - ya_j}\right| \geq \sqrt{D}.
\]

9. Proof of Proposition 3.2 for Forms of signature (4, 0)

Let $(x, y) \neq (1, 0)$ be a pair of solution to (1) and
\[
\phi(x, y) = \phi(1, 0) + \sum_{k=2}^{r+s} m_k \log (\tau(\lambda_k)), \quad m_k \in \mathbb{Z}.
\]

Let us set $t = \frac{x}{y}$ and define
\[
T_{i,j}(t) := \log \left|\frac{(t - \alpha_i)(\alpha_4 - \alpha_j)}{(t - \alpha_j)(\alpha_4 - \alpha_i)}\right|.
\]

Notice that
\[
T_{i,j}(x, y) = T_{i,j}(t) = \log \left|\frac{\alpha_4 - \alpha_i}{\alpha_4 - \alpha_j}\right| + \log \left|\frac{t - \alpha_j}{t - \alpha_i}\right|
\]
\[
= \log \left|\frac{\alpha_4 - \alpha_i}{\alpha_4 - \alpha_j}\right| + \log \left|\frac{x - \alpha_j y}{x - \alpha_i y}\right|
\]
\[
= \log |\lambda_{i,j}| + \sum_{k=2}^{4} m_k \log \frac{|\lambda_k|}{|\lambda_k'|},
\]

where $\lambda_{i,j} = \log \left|\frac{x - \alpha_i y}{x - \alpha_j y}\right|$ and $\lambda_k$ and $\lambda'_k$ are fundamental units in $\mathbb{Q}(\alpha_j)$ and $\mathbb{Q}(\alpha_i)$, respectively.

**Lemma 9.1.** Let $(x, y)$ be a pair of solution to (1) with $|y| \geq M(F)^{3,5}$. Then there exists a pair $(i, j)$ for which
\[
|T_{i,j}(x, y)| < \exp \left(-\frac{\|\phi(t)\|}{6}\right).
\]

**Proof.** This is a consequence of Lemma 7.2 and the proof goes exactly the same as the proof of Lemma 6.8 in [2]. \qed

Let index $\sigma$ be the isomorphism from $\mathbb{Q}(\alpha_i)$ to $\mathbb{Q}(\alpha_j)$ such that $\sigma(\alpha_i) = \alpha_j$. We may assume that $\sigma(\lambda_i) = \lambda'_i$ for $i = 2, 3, 4$. Let $(x_1, y_1), (x_2, y_2), (x_3, y_3)$ be three distinct solutions to (1) with
\[
y_k \geq M(F)^{3,5}
\]
and
\[
|x_k - \alpha_4 y_k| = \min_{1 \leq i \leq 4} |x_k - \alpha_i y_k|, \quad k \in \{1, 2, 3\}.
\]

This assumption will lead us to a contradiction at the end of this section, implying that related to each real root of $F(x, 1) = 0$, there are at most 2 solutions with $y \geq M(F)^{3,5}$. Recall that related to a non-real root, there exists no such solution.

Put $r_k = \|\phi(x_k, y_k)\|$ and assume that $r_1 \leq r_2 \leq r_3$. We will apply Matveev’s lower bound to
\[
T_{i,j}(x_3, y_3) = \log |\lambda_{i,j}| + \sum_{k=2}^{r+s} m_k \log \frac{|\lambda_k|}{|\lambda_k'|},
\]
where \((i, j)\) is chosen so that Lemma 9.1 is satisfied and \(m_k \in \mathbb{Z}\). Forms of signature \((0, 2)\) have one fundamental unit and forms of signature \((2, 1)\) have two fundamental units. Moreover, if \(\lambda_{i,j}\) is a unit then we can write \(T_{i,j}(x, y)\) as a linear form in fewer number of logarithms. We remark here that when dealing with linear forms in 2 logarithms, one can use sharper lower bounds (see for example [6]).

Suppose that \(\lambda\) is a unit in the number field and \(\lambda'\) is its algebraic conjugate. We have

\[
h(\lambda') = h(\lambda) = \frac{1}{8} \left\| \log (\tau(\lambda)) \right\|_1,
\]

where \(h\) is the logarithmic height and \(\left\| \cdot \right\|_1\) is the \(L_1\) norm on \(\mathbb{R}^4\) and the mappings \(\tau\) and \(\log\) are defined in (18) and (19). So we have

\[
h(\lambda) = \frac{1}{8} \left\| \log (\tau(\lambda)) \right\|_1 \leq \frac{\sqrt{4}}{8} \left\| \log (\tau(\lambda)) \right\|,
\]

where \(\left\| \cdot \right\|\) is the \(L_2\) norm on \(\mathbb{R}^{r+s-1}\). Since \(\alpha_4, \alpha_i\) and \(\alpha_j\) have degree 4 over \(\mathbb{Q}\), the number field \(\mathbb{Q}(\alpha_4, \alpha_i, \alpha_j)\) has degree \(d \leq 24\) over \(\mathbb{Q}\). So when \(\lambda\) is a unit

\[
\max \{dh\left(\frac{\lambda}{\lambda'}\right), \left\| \log \left(\frac{\lambda}{\lambda'}\right) \right\| \} \leq \max \{24h\left(\frac{\lambda}{\lambda'}\right), \left\| \log \left(\frac{\lambda}{\lambda'}\right) \right\| \} \leq 12 \left\| \log (\tau(\lambda)) \right\|.
\]

In order to apply Theorem 2.5 to \(T_{i,j}(x, y)\), we will take, for \(k > 1\),

\[
A_k = 12 \left\| \log (\tau(\lambda)) \right\|.
\]

By (21) and Lemma 8.2, we have

\[
A_k \leq 24\left\| \phi(x, y) \right\|, \quad \text{for } k > 1.
\]

Now we need to estimate \(A_1\).

**Lemma 9.2.** Let \(F\) be an irreducible binary quartic form with integral coefficients. Assume that \((x, y)\) is a solution to (1) with \(y \geq M(F)^{3.5}\). Then, we have

\[
h\left(\frac{\alpha_k - \alpha_i}{\alpha_k - \alpha_j}\right) \leq 2 \log 2 + 2\left\| \phi(x, y) \right\|.
\]

**Proof.** Let \(\beta_i = x - y\alpha_i\). We have

\[
\frac{\alpha_k - \alpha_i}{\alpha_k - \alpha_j} = \frac{\beta_k - \beta_i}{\beta_k - \beta_j}.
\]

Thus by (5) and (6),

\[
h\left(\frac{\alpha_k - \alpha_i}{\alpha_k - \alpha_j}\right) \leq 2 \log 2 + 4h(\beta_k).
\]

To complete the proof, we will show that

\[
h(\beta_k) \leq \frac{1}{2} \left\| \phi(x, y) \right\|.
\]

Set

\[
v_i = \log |\beta_i| = \phi_i(x, y) - \phi_i(1, 0) \quad \text{for} \quad i \in \{1, 2, 3, 4\}
\]

and

\[
\vec{v} = (v_1, v_2, v_3, v_4).
\]

Since \(\beta_k\) is a unit, we have

\[
h(\beta_k) = \frac{1}{8} \sum_{i=1}^{4} |v_i| = \frac{1}{8} (s_1, s_2, s_3, s_4) \cdot \vec{v},
\]
where \( s_1, s_2, s_3, s_4 \in \{+1, -1\} \). Since \( \|(s_1, s_2, s_3, s_4)\| = 2 \), we obtain
\[
h(\beta_k) \leq \frac{1}{4} \|\vec{v}\|.
\]
On the other hand, we have
\[
\|\vec{v}\| \leq \|\phi(x, y)\| + \|\phi(1, 0)\| \leq 2\|\phi(x, y)\|.
\]
This completes our proof. \( \square \)

Set, for \( k \in \{1, 2, 3\} \),
\[
r_k = \|\phi(x_k, y_k)\|.
\]

We may take
\[
A_1 = 48 \log 2 + 48r_1
\]
(recall that \( \alpha_1, \alpha_i, \alpha_j \) are algebraic conjugates). Since \( m_1 = 1 \), we will put
\[
B = \max\{1, \max\{m_j A_j / A_1 : 1 \leq j \leq 4\}\}.
\]
Since we assumed that \( \tau(\lambda_i) \), \( 2 \leq i \leq r+s-1 \) are successive minima for the lattice \( \Lambda \), we have
\[
|m_j A_j| \leq r_3 + \|\phi(1, 0)\| < 2r_3.
\]
Thus we may take \( B = \frac{r_3}{12} \) (see (21)).

Proposition 2.5 implies that for a constant number \( K \),
\[
\log T_{i,j}(x_3, y_3) > -Kr_4^4 \log r_3.
\]
Comparing this with Lemma 9.1, we have
\[
\left(\frac{-r_3}{6}\right) > -Kr_4^4 \log r_3,
\]
or
\[
\frac{r_3}{\log r_3} < 6Kr_4^4.
\]
Thus there is a computable constant number \( K_1 \), so that
(25) \[
r_3 < K_1 r_4^4,
\]
This is because \( r_3 \) is large enough by Lemma 8.4. But by Lemma 7.1 we have
\[
r_3 > 0.00014 \exp\left(\frac{r_1}{6}\right).
\]
This is a contradiction, for by Lemma 8.4,
\[
r_1 \geq \frac{1}{2} \log \left(\frac{|D|^{1/2}}{2}\right)
\]
and \( D \) is large. Thus, there are at most 2 solutions \( (x, y) \) with \( y \geq M(F)^{3.5} \) related to each real root \( \alpha_i \). The proof of Proposition 3.2 for forms with signature \((4, 0)\) is complete now. This argument can be used for forms with signature \((2, 1)\), as well and will give us an bound of 17 upon the number of solutions to (1) for this case. In the next section, we will see that for forms of signature \((2, 1)\) we do not need to consider the set \( \mathfrak{A} \), as the lattice generated by the fundamental units of the corresponding number field is contained in a plane.
10. Proof of Proposition 3.2 for Forms of signature (2, 1)

Let \( F(x, y) \) be a quartic form of signature (2, 1). Suppose that \((x_1, y_1), (x_2, y_2)\) and \((x_3, y_3)\) are three pairs of non-trivial solution to (1) with

\[
|x_j - \alpha_4 y_j| < 1,
\]

and \(|y_j| > M(F)^{3.5}\), for \( j \in \{1, 2, 3\} \). We will assume \( \alpha_4 \) is real (recall that related to a non-real root, there exists no solution \((x, y)\) with \(|y| > M(F)^{3.5}\)). The real number field \( \mathbb{Q}(\alpha_4) \) has two fundamental units \( \lambda_2, \lambda_3 \) chosen so that \( \log(\tau(\lambda_2)), \log(\tau(\lambda_3)) \) are successive minimas of the lattice \( \Lambda \), with

\[
\| \log(\tau(\lambda_2)) \| \| \log(\tau(\lambda_3)) \| \geq \frac{2}{\sqrt{3}} \text{Vol}(\Lambda),
\]

where \( \text{Vol}(\Lambda) \) is the volume of fundamental parallelepiped of lattice \( \Lambda \). If \((x, y)\) is a solution to \(|F(x, y)| = 1\), then

\[
\phi(x, y) \in \phi(1, 0) + \Lambda = \Lambda_1.
\]

Note that

\[
\text{Vol}(\Lambda) = \text{Vol}(\Lambda_1).
\]

For distinct pairs of solution \((x_1, y_1), (x_2, y_2)\) and \((x_3, y_3)\), three vectors \(\phi(x_1, y_1), \phi(x_2, y_2)\) and \(\phi(x_3, y_3)\) generate a sub-lattice of \(\Lambda_1\) with the volume of fundamental parallelepiped equal to \(2A\). Therefore,

\[
2A \geq \text{Vol}(\Lambda_1) = \text{Vol}(\Lambda).
\]

On the other hand, by (17), \( A \), the area of \( \Delta \) is less than

\[
2 \|\phi(x_3, y_3)\| \exp\left(-\|\phi(x_1, y_1)\|/6\right).
\]

This, together with (27) gives

\[
\|\phi(x_3, y_3)\| > \frac{\text{Vol}(\Lambda)}{4} \exp\left(\frac{\|\phi(x_1, y_1)\|}{6}\right).
\]

Let us replace Proposition 7.1 by the above inequality when \( F(x, y) \) has signature (2, 1).

Put \( r_k = \|\phi(x_k, y_k)\| \) and assume that \( r_1 \leq r_2 \leq r_3 \). We will apply Matveev’s lower bound to

\[
T_{i,j}(x_3, y_3) = \log |\lambda_{i,j}| + \sum_{k=2}^{r_3+s} m_k \log |\lambda_k|/|\lambda_k|,
\]

where \((i, j)\) is chosen so that Lemma 9.1 is satisfied and \( m_k \in \mathbb{Z} \). Similar to Section 9, let index \( \sigma \) be the isomorphism from \( \mathbb{Q}(\alpha_i) \) to \( \mathbb{Q}(\alpha_j) \) such that \( \sigma(\alpha_i) = \alpha_j \). We may assume that \( \sigma(\lambda_i) = \lambda_i' \) for \( i = 2, 3, 4 \). Recall that related to a non-real root, there exists no such solution.

We use our estimation from Section 9 for \( A_1 \) and \( B \):

\[
A_1 = 48 \log 2 + 48 r_1
\]

and

\[
B = \frac{r_3}{12}
\]

For fundamental units \( \lambda_k \), with \( k \in \{2, 3\} \), using (24), we may put

\[
A_k = 12 \|\log(\tau(\lambda))\|.
\]
Theorem 2.5 and (26) imply that for a constant number $K$,
$$\log T_{i,j}(x_3, y_3) > -K r_1 \log r_3 \text{Vol}(\Lambda).$$
Comparing this with Lemma 9.1, we have
$$\left(-\frac{r_3}{6}\right) > -K r_1 \log r_3 \text{Vol}(\Lambda),$$
or
$$\frac{r_3}{\log r_3} < 6Kr_1 \text{Vol}(\Lambda).$$
Thus, since $r_3$ is large enough by Lemma 8.4, there is a computable constant number $K_2$, so that
$$r_3 < K_2 r_1 \text{Vol}(\Lambda)$$
(compare this with (25)). But by (28) we have
$$r_3 > \frac{\text{Vol}(\Lambda)}{4} \exp \left(\frac{r_1}{6}\right).$$
Consequently, for some positive constant $K_3$,
$$r_1 > K_3 \exp \left(\frac{r_1}{6}\right).$$
This is a contradiction by Lemma 8.4 and since the discriminant is large. Thus, there are at most 2 solutions $(x, y)$ with $y \geq M(F)^{3.5}$ related to each real root $\alpha_i$. The proof of Proposition 3.2 and Theorem 1.1 are complete now.

11. Acknowledgements

I would like to thank Professor Ryotaro Okazaki for his helpful comments and suggestions. Most of this work has been done during my visit to mathematisches forschungsinstitut oberwolfach and Max-Planck institute for mathematics in Bonn. I am very grateful to both institutes for support and hospitality.
